Psych 215L: Language Acquisition

Lecture 4 Speech Perception I

Sounds of Language (Speech Perception)

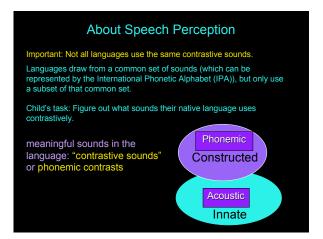

Learner's job: Identify phonemes (contrastive sounds that signal a change in meaning)

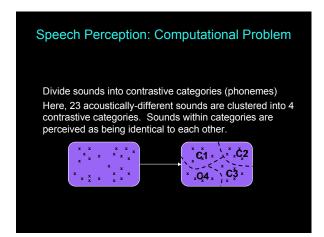

big vs. pig

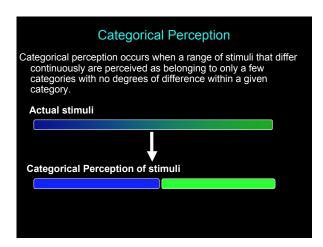

Phonemes are language-specific - r/l Lisa = Risa for some is a phonemic contrast in English but of my Japanese not in Japanese friends

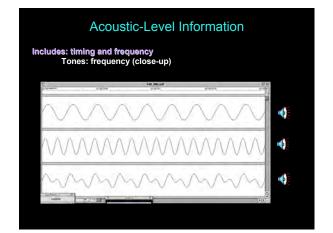

Kids of the world require knowledge of phonemes before they can figure out what different words are - and when different meanings are signaled by different words

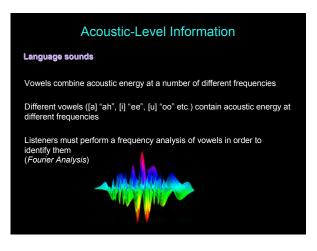

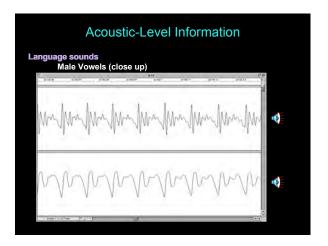

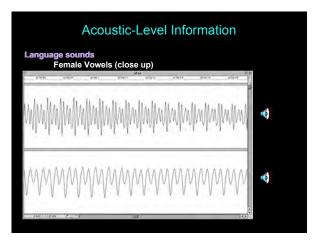

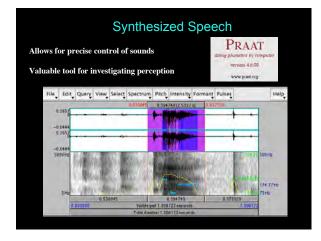

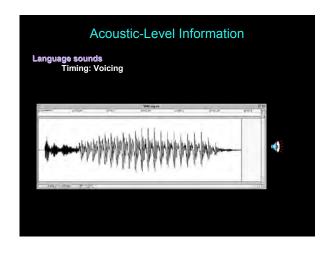

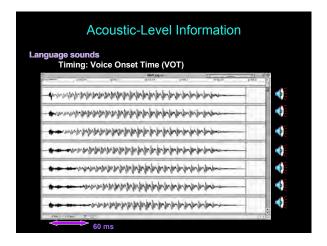

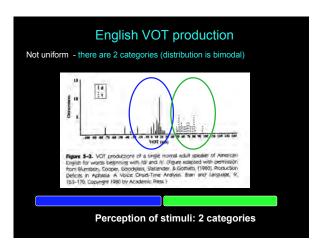

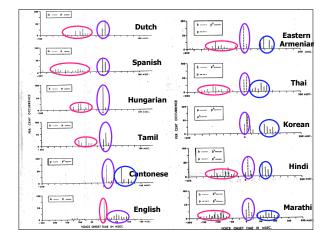

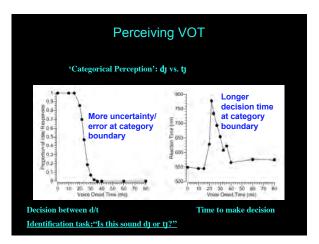

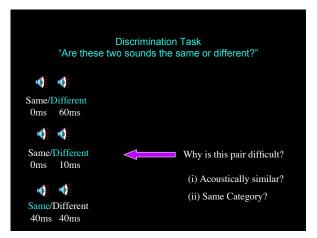

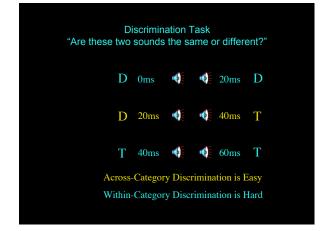

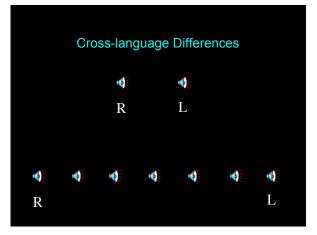

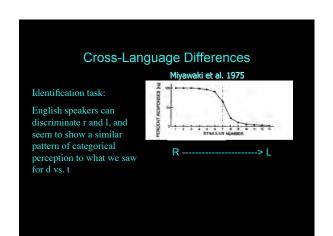

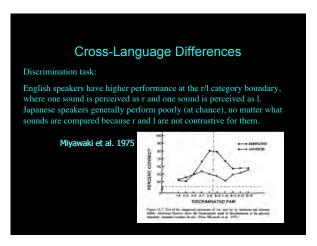

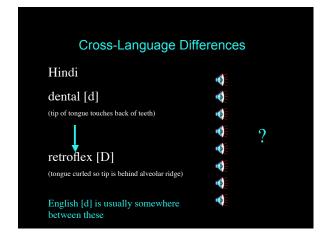

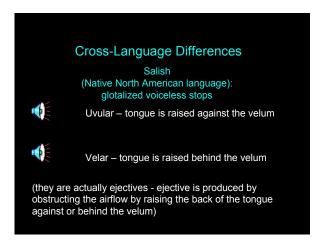

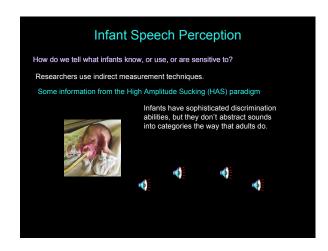

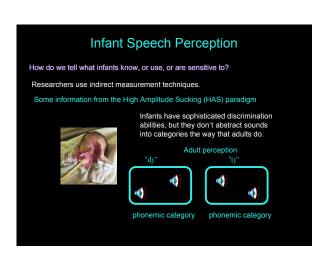

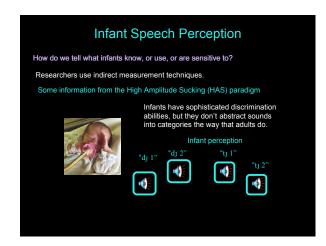

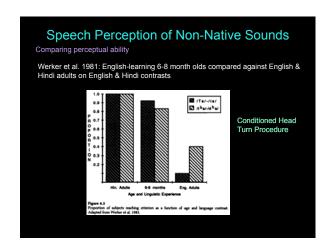

Werker (1995): Speech Perception But when after 6-8 months is the ability to lost? Key into "critical period" hypothesis for language (Lenneberg 1967) - when language can be learned natively "To test for this critial period, children of 12 and 8 years were tested, with the expectation that the 8-year-olds but not the 12-year-olds would be able to discriminate nonnative contrasts. English-speaking children of both ages, however, performed like English-speaking adults...study was extended to 4-year old children, who actually performed most poorly of all on nonnative contrasts...findings revealed that experience must begin to influence speech perception long before 4, certainly well before the critical period suggested by Lenneberg."

Speech Perception of Non-Native Sounds But when after 6-8 months is the ability to lost? Werker & Tees (1984) Salish & Hindi contrasts Change happens somewhere around 8-10 months, depending on the sound contrast.

Discovering contrastive sounds: What's the point of it again?

The idea is that once children discover the meaningful sounds in their language, they can begin to figure out what the words are.

Ex: An English child will know that "cat" and "caat" are the same word (and should have the same meaning).

As adults, we can look at a language and figure out what the contrastive sounds are by looking at what changes a word's meaning. But children can't do this - they figure out the contrastive sounds *before* they figure out words and word meanings.

More about contrastive sounds

There are a number of acoustically salient features for sounds. All it takes for sounds to be contrastive is for them to have "opposite" values for one feature.

Example:

English sounds "k" and "g" differ only with respect to voicing. They are pretty much identical on all other features. Many contrastive sounds in English use the voicing feature as the relevant feature of contrast (p/b, t/d, s/z, etc.). However, there are other features that are used as well (air flow, manner of articulation, etc.).

Task for the child: Figure out which features are used contrastively by the language. Contrastive sounds for the language will usually vary with respect to one of those features.

Experimental Study: Dietrich, Swingley & Werker (2007)

Testing children's perception of contrastive sounds

Dutch and English contrastive features differ.

In English, the length of the vowel is not contrastive

"cat" = "caat"

In Dutch, the length of the vowel is contrastive

"cat" ≠ "caat"

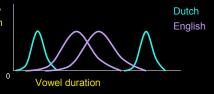

(Japanese also uses this feature)

Does the data distribution show this?

Dutch and English vowel sounds in the native language environment also seem to differ

"...studies suggest that differences between the long and short vowels of Dutch are larger than any analogous differences for English."

Frequency of sound in input

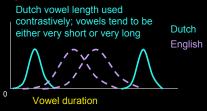

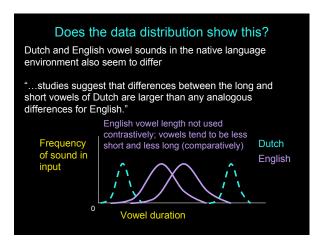

Does the data distribution show this?

"...studies suggest that differences between the long and short vowels of Dutch are larger than any analogous differences for English."

Frequency of sound in input

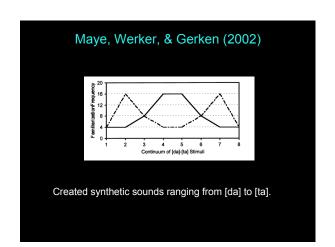

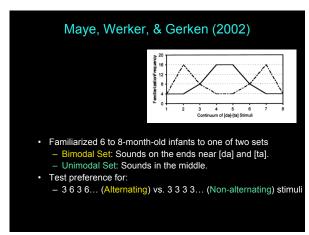

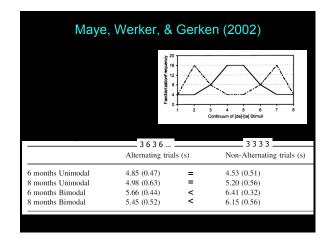

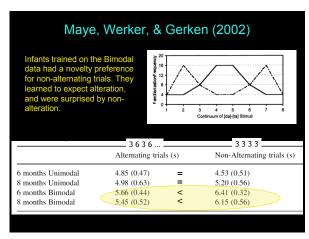

How do we know that children are sensitive to distributional information?

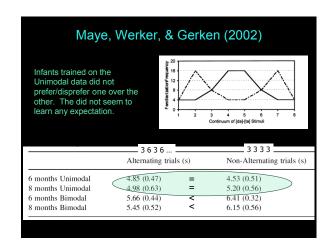

Learning from real data distributions

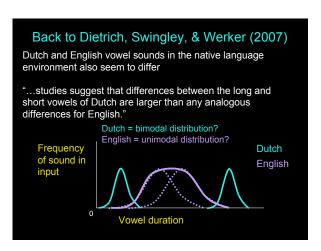

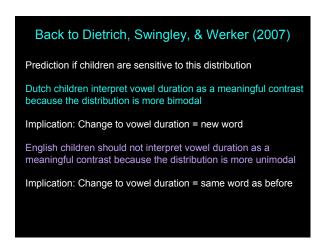

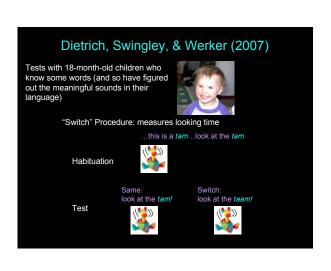

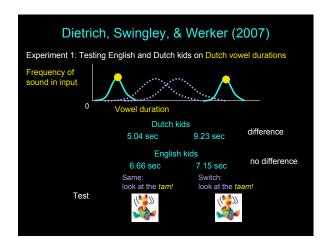

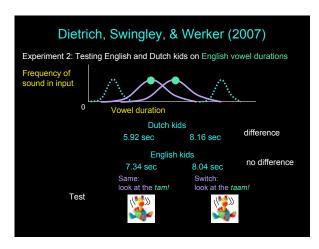

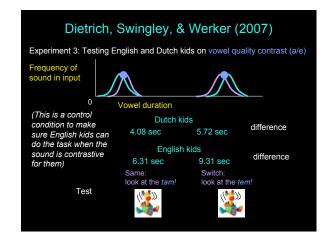

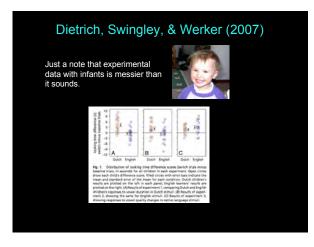

Dietrich, Swingley, & Werker (2007) Implications of experiments 1, 2, and 3: Dutch children recognize vowel duration as contrastive for their language while English children do not. This can only be due to the data encountered by each set of children in their language. Dutch children have a category boundary approximately here. English children do not. Frequency of sound in input Outch English Vowel duration

What drives children to learn the distinction?

"One frequently raised hypothesis...is that it is driven by contrast in the vocabulary. Dutch children might learn that [a] and [a:] are different because the words [stat]...and [sta:t]...mean different things...however, children that young do not seem to know many word pairs that could clearly indicate a distinction between [a] and [a:]."

Dietrich, Swingley, & Werker (2007)

"The other current hypothesis is that children begin to induce phonological categories "bottom-up", based on their discovery of clusters of speech sounds in phonetic space...undoubtedly implicated in infants' early phonetic category learning, which begins before infants know enough words for vocabulary-based hypotheses to be feasible..."

Dietrich, Swingley, & Werker (2007)

"A necessary condition for such learning to be the driving force behind Dutch children's phonological interpretation in the present studies is that long and short vowels be more clearly separable in Dutch than in English...preliminary examination of this problem using corpora of Dutch child-directed speech indicated that the set of long and short instances formed largely overlapping distributions."
