# Psych 56L/ Ling 51: Acquisition of Language

Lecture 15
Language & Cognition

#### Announcements

Be working on HW3

Review questions available for language and cognition

Please fill out course evaluations for this class

Remember to look at extra credit options (especially the first one, which is a webgame)

# Sapir Whorf Hypothesis

The structure of one's language influences the manner in which one perceives and understands the world.

"Don't you see that the whole aim of Newspeak is to narrow the range of thought? In the end, we shall make thought crime literally impossible, because there will be no words in which to express it..." - George Orwell, 1984

# "Neo"-Whorfian Question

Language as a Toolkit: Does language augment our capacity for reasoning and representation?

Also sometimes referred to as "language as augmenter" (Wolff & Holmes 2010)

#### What the language toolkit can do

Language is a symbolic system that can help with cognitive off-loading.

# Cognitive Off-Loading example (from Wolff & Holmes 2010)

FIGURE 3 | Series of gears in which the first turns clockwise. In which direction will the last gear turn?

"This problem could be solved by mental simulation; that is, by imagining the first gear turning to the right, then the second gear turning to the left, and so on. Alternatively, people might notice that each successive gear turns in the opposite direction from the previous one and generate the parity rule that 'odd and even gears turn in different directions'. This rule, which may depend on linguistic coding, can then be applied more quickly than the laborious process of mentally rotating each gear."

# Language as a Toolkit

#### Today:

Navigation (combining core knowledge system information)

→ geometric + landmark or color information

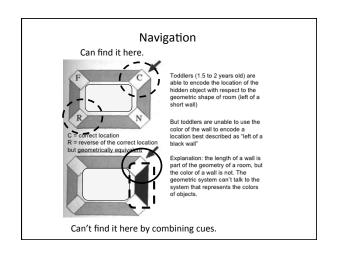

Number (combining core knowledge system information)

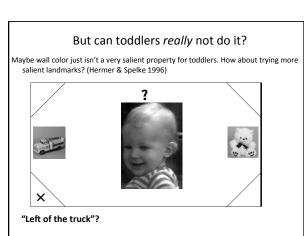

→ small, exact numbers & large, approximate numbers

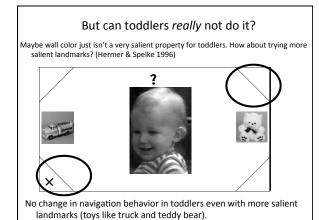

#### Next time:

Theory of Mind (realizing that someone can have a different point of view than you - when does this realization come, and how?)

#### Navigation Geometric Combination Object Landmark "At the northeast 'Northeast of the "At the (blue) corner" (blue) cylinder" cylinder" × \*rats \*adult humans ONLY \*rats \*human infants \*human infants \*adult humans \*adult humans

# So when does this ability develop?

Hermer-Vazquez, Moffet & Munkholm 2001: children with a high production of spatial language (like "left" and "right") succeed. This usually happens somewhere between 4 and 5 years old.

Shusterman, Lee, & Spelke 2011: 4-year-old children can combine spatial and landmark cues when specifically told a landmark will be useful for navigation. (Ex: "The black wall can help you get the sticker.")

Hyde, Winkler-Rhoades, Lee, Izard, Shapiro, & Spelke 2011: a 13-yearold deaf child, deprived of most linguistic input after late infancy, performs like toddlers do (very poor when cues must be combined to solve navigation).

# So when does this ability develop?

Implication: Language use seems integral in solving this task that requires representing information from different domains (geometry & color). Children can be prompted through language to pay attention to it, but without language, it seems difficult for humans to solve these kind of tasks.

# So when does this ability develop?

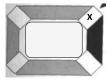

However... rats (who don't have spatial language) can be trained to do the same thing, though only after hundreds of trials. Language is useful (speeds things up), but not necessary?

# Is language really responsible?

Hermer-Vazquez, Spelke & Katnelson 1999

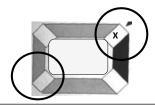

Testing adults, who were asked to verbally shadow as they performed the task. Verbal shadowing (language as meddler: Wolff & Holmes (2010)) = repeating as fast as they could a passage recorded on tape. Interferes with linguistic combination abilities. [Class demo of verbal shadowing: repeat a passage while imagining that you're giving precise directions from here to the student union.]

# Is language really responsible?

Hermer-Vazquez, Spelke & Katnelson 1999

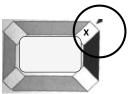

Verbal-shadowing adults behaved just like toddlers! They searched equally the correct corner and the rotationally equivalent one, seemingly unable to combine the information from geometry and color.

#### Is language really responsible?

Hermer-Vazquez, Spelke & Katnelson 1999

Experiments with adults who were doing nonverbal shadowing (repeating a rhythm by clapping) did not show this result, despite the fact that the nonverbal shadowing (rhythm shadowing in this case) is as cognitively taxing as verbal shadowing. [Class demo of rhythm shadowing: repeat the clapping pattern while imagining that you're giving precise directions from here to the student center.]

#### Is language really necessary?

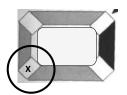

Gouteux, Thinus-Blanc, & Vauclair 2001: testing Rhesus monkeys (who do not have spatial language)

Tested 3 monkeys on location "left of wall opposite the blue wall". ~50 trials each.

Two monkeys: ~85% correct Other monkey: ~70% correct

Pretty good for no spatial language!

# Is language really necessary?

So language *does* seem to play a very important role in the ability to combine information from different core knowledge systems. (Perhaps not absolutely necessary, but extraordinarily helpful - kind of like motherese for language development.)

Or maybe rhesus monkeys are just clever enough to do this without the spatial language that humans seem to rely on. Maybe humans rely on language because they have it as a tool at their disposal...

#### Number

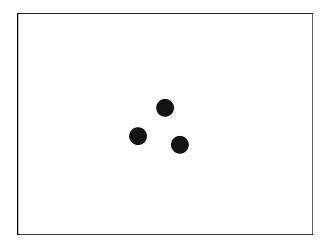

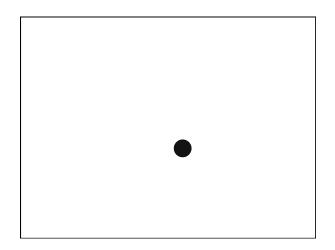

Core number systems shared by humans and other animals:

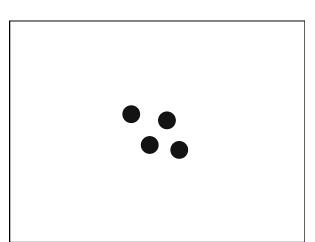

System for representing approximate numerical magnitudes (large, approximate number sense)

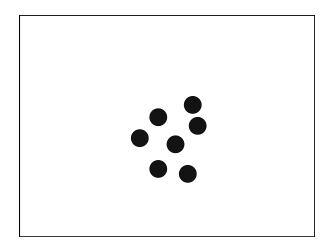

System for representing persistent, numerically distinct individuals (small, exact number sense)

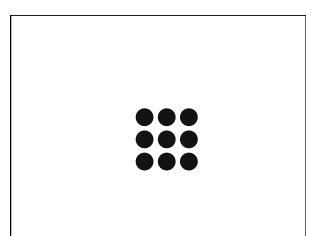

Decide Fast: How Many?

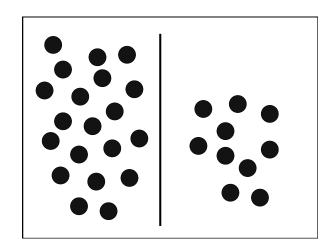

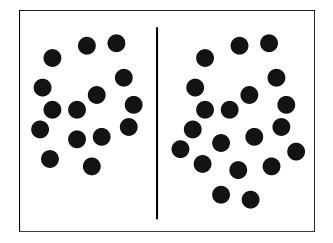

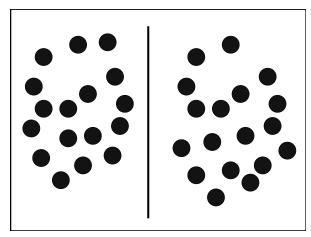

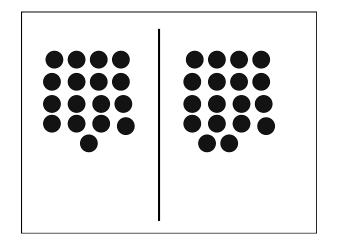

Decide Fast: Which side has more?

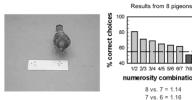

Amount Being Represented	How Represented
Very small numbers	"Subitizing"- up to 4; can tell what set looks like at a glance
Large approximate numerosities	System for representing approximate numerical magnitudes (adults at a glance can tell apart groups with a ratio of about 1.1 to 1 [Weber's Law])
Large exact numerosities	Combo of 2 above systems plus language

#### A number sense in general isn't special

Prelinguistic infants have a system for approximating numerical magnitudes (Dehaene 1997, Gallistel & Gelman 2000), but so do pigeons, rats, fish, and other primates.

# Weber Fraction Limit for telling apart large numerosities

Age	Weber fraction
6 months	1.5-2
9 months	1.2-1.5
adult	1.15

#### Everyone can do:

12 vs. 6 = 2.0 32 vs 16 = 2.0 100 vs 50 = 2.0

6 month olds struggle:

12 vs. 8 = 1.5

9 month olds struggle:

12 vs. 10 = 1.2

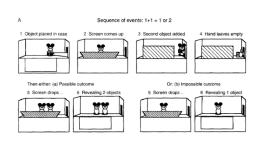

Adults struggle:

12 vs. 11 = 1.09

# What about small numbers?

#### Wynn 1998:

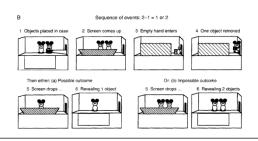

Testing infant knowledge using a preferential looking paradigm. Infants are surprised by the "impossible" outcome, which means they can do addition on very small numerosities precisely.

# What about small numbers?

#### Wynn 1998:

Testing infant knowledge using a preferential looking paradigm. Infants are surprised by the "impossible" outcome, which means they can do subtraction on very small numerosities precisely.

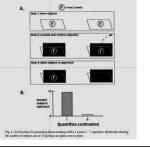

# What about small numbers?

Sulkowski & Hauser 2001: Monkeys can, too

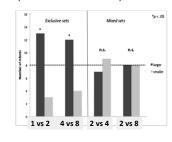

- Rhesus monkeys shown to spontaneously represent the numbers 1-3
- Test monkeys by using a procedure predicated on monkeys going to where they think food is
   (28 Mathematic NR Better / Completion 79 (289) 2879 282 287

#### What about small vs. approximate numbers?

vanMarle 2012: 10- to 12-month-old infants have trouble doing comparisons across these two systems

"Infants choosing between sets that were either exclusively small (1 vs. 2) or exclusively large (4 vs. 8) chose the larger amount significantly more often than chance. Infants choosing between "mixed" sets, where one quantity was small and one was large, performed at chance. n.s., nonsignificant."

# What human language does...

Many languages have an *exact* number system that provides names for exact quantities of any size

1, 2, 3, 4, 5......578, 579, 580, 581, 582...

This bridges the "gap" between the two core systems.

Supporting evidence from Dehaene, Spelke, Pinel, Stanescu, and Tsivkin 1999: fMRI study showed that the exact number task recruited neural networks typically associated with language processing.

# What human language does...

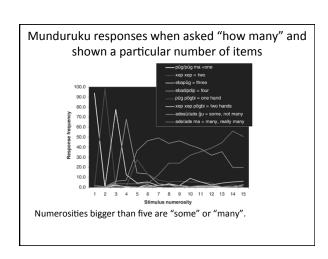

Many languages have an *exact* number system that provides names for exact quantities of any size

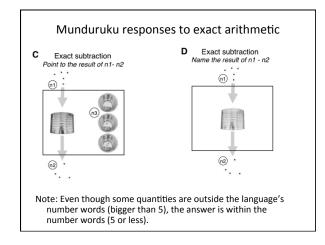

1, 2, 3, 4, 5......578, 579, 580, 581, 582...

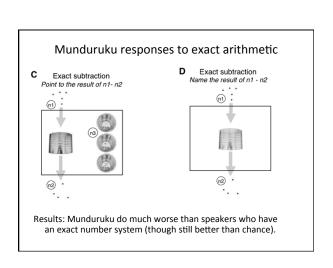

This bridges the "gap" between the two core systems.

Another test of this: Look at the numerical cognition of people whose languages don't have an exact number system.

# Pica, Lemer, Izard & Dehaene 2004: Munduruku speakers in Brazil who only have exact numbers for 1-5. \*\*Manduruku main territory\*\* \*\*Andara Andara A

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

**Table 1.** Use of fingers and number words by Pirahā participant. The arrow  $(\rightarrow)$  indicates a shift from one quantity to the next.

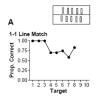

No. of objects	Number word used	No. of fingers
1	hói (= 1)	
2	hoí (= 2)	2
	aibaagi (= many)	
3	hoí (= 2)	3
4	hoí (= 2)	$5 \rightarrow 3$
	aibai (= many)	
5	aibaagi (= many)	5
6	aibaagi (= many)	$6 \rightarrow 7$
7	hói (= 1)*	1
	aibaagi (= many)	5 → 8
8		$5 \rightarrow 8 \rightarrow 10$
9	aibaagi (= many)	5 → 10
10		5

\*This use of "one" might have been a reference to adding one rather than to the whole set of objects.

#### **Languages without Exact Number Systems**

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown batteries on one side of the line, and asked to line up batteries to match on the other side.

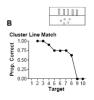

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

> Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do.

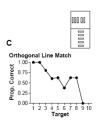

Shown cluster of nuts on one side of the line, and asked to line up batteries to match on the other side.

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

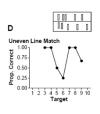

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown vertical line of batteries on one side, and asked to line up batteries to match on the other side.

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

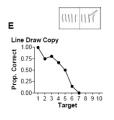

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown uneven line of batteries on one side, and asked to line up number of batteries to match on the other side.

#### Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

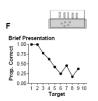

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown lines on one side, and asked to copy number of lines to match on the other side.

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown cluster of nuts on one side for one second, and then asked to match number of batteries to that amount from memory.

# Languages without Exact Number Systems

Gordon 2004: Pirahã speakers in Brazil who only have words for "one/two" and "many".

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard to do. Shown cluster of nuts, and then nuts are placed in a can. One nut is withdrawn at a time, and participant asked after each one if the can is empty yet.

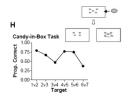

#### Languages without Exact Number Systems

in Brazil who only have words for "one/two" and "many".

Exact arithmetic on larger numbers that are both outside the small, exact system and outside the language is very, very hard

Gordon 2004: Pirahã speakers Candy put in a box with a given number of fish drawn on the top of the box. The box is then hidden. The box is then brought out again along with another box with either one more or one fewer fish painted on the box. Participants asked to identify which box contains the

#### Gelman & Gallistel 2004: "Language and the Origin of Numerical Concepts"

"Reports of subjects who appear indifferent to exact numerical quality even for small numbers, and who also do not count verbally, add weight to the idea that learning a communicable number notation with exact numerical reference may play a role in the emergence of a fully formed conception of number." fully formed conception of number.

No language for large exact numbers = no representation for large exact numbers

# Languages without Exact Number Systems

#### http://xkcd.com/1070/

JUST TO CLEAR THINGS UP:		
A FEW	ANYWHERE FROM 2 TO 5	
A HANDFUL	ANYWHERE FROM 2 TO 5	
SEVERAL	ANYWHERE FROM 2 TO 5	
A COUPLE	2 (BUT SOMETIMES UP TO 5)	

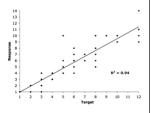

Note: English has imprecise words for numbers, too – but we also have exact words for numbers.

#### Another example: deaf people who have not had access to a language (spoken or signed)

Spaepen, Coppola, Spelke, Carey, & Goldin-Meadow 2011 Test population: Home-signers from Nicaragua

Spontaneous communication about number: The number of fingers the home-signers extended (y axis) as a function of the number of objects actually shown in a story they were retelling (x axis).

Home-signers seem able to track approximate numerosity.

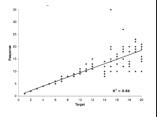

Another example: deaf people who have not had access to a language (spoken or signed)

Spaepen, Coppola, Spelke, Carey, & Goldin-Meadow 2011 Test population: Home-signers from Nicaragua

Asked to relate *exactly* how many objects were shown.

Home-signers have major difficulty once numbers go much above four.

#### Children's numerical cognition

- English children must learn number words, and it can take them a surprisingly long time to do it.
- Even if children can recite a list of counting numbers ("one, two, three, four, five, ..."), they may not necessarily understand that "three" refers to the quantity three. Moreover, even if they recite the list when seeming to count objects, they do not realize that the last number they say is the right answer.

Investigator: "How many are there?"
Child: "One, two, three, four, five. There are three!"

Barbara Sarnecka

# Children's numerical cognition

• The process of connecting number words to quantity seems to occur in stages:

Pre-number-knowers: no number word knowledge

One-knowers: "one", but no other numbers
Two-knowers: "one", "two", but no others
Three-knowers: "one", "two", "three", but no

Cardinal-principle-knowers: children realize the connection between the counting list and quantity (cardinal principle of counting) – the last number you say is in the list is the quantity (denotes the cardinality of the set)

Barbara Sarnecka

# Children's numerical cognition

Negen & Sarnecka (2010): Tested children's non-verbal numerical cognition when they did not necessarily know the exact meaning of number words.

"Now we're going to play a *copying* game. I will give something to the anteater...(experimenter puts some items from a bowl onto his plate, and slides it to his stuffed animal)...and you give something to the bunny. You copy me and make your plate look *just like mine*."

"Now we're going to play a remembering game. I will give something to the bunny...(experimenter demonstrates)...and you try to remember what I gave the bunny. (Experimenter returns items to the bowl.) You give the bunny something and try to make yours just like mine was."

# Children's numerical cognition

Negen & Sarnecka (2010): Tested children's non-verbal numerical cognition when they did not necessarily know the exact meaning of number words.

Results: Children who know more number words did a better job at replicating and remembering the number of items. Surprisingly, performance improved for all number sizes, even the ones children didn't necessarily have words for yet.

Example: Child knows "one" and "two", but improves at replicating/ remembering not only one and two, but also three, four, and five objects.

Language for numbers helps improve non-verbal comprehension and memory for numbers - helps highlight the salient concept of quantity.

#### Language & Cognition: Recap

Whorfianism is the belief that language influences (or determines) someone's experiences in the world. Neo-Whorfianism is a variant that believes language augments thought, so we can think more complex thoughts.

In both navigation and number, we have seen evidence for cases where language seems to enable more complex thought - or at least to enable it to happen more easily.

# Questions?

You should be able to answer up through question 15 on the language & cognition review questions, and up through question 8 on HW3.
